Focused sensitivity analysis: A.1.2 coordinator roles

Matched comparison of identical genuine evidence with and without five low-quality controls

Design and analytical distinction

The redesigned experiment isolated A.1.2, which assesses whether the national coordinator's role is known and identified. The control-free condition contained 60 genuine evaluation records previously rated strong. The treatment contained the identical 60 records in the same relative order plus five A.1.2 controls. The scoring scope, frozen Stage 2 P5 prompt, model, temperature (0), output schema and validation procedure were identical. Neutral EV-#### identifiers concealed record type.

Positive justification use and contrary/limiting use were treated as opposing categories. A control counted as positively used only when it appeared in evidence_supporting_score. Controls appearing only in contrary_or_limiting_evidence were classified as limiting references, not positive justification evidence.

Matched result

Condition	Evidence bank	Phase	Genuine support	Control role
Original full-pipeline final	622 genuine records	3	8 records	Not applicable
Matched control-free	60 identical genuine records	2	6 records	No controls
Matched fake-source treatment	Same 60 genuine + 5 controls	2	2 records	0 positive; 4 limiting; 1 ignored

The phase remained stable at Phase 2 after control injection. None of the controls was used positively. Four were assigned exclusively to the limiting-evidence field and the generic external comment was ignored. The experiment therefore shows score-level robustness for A.1.2.

Role assigned to each control

Evidence ID	Control construction	Positive use	Assigned role
EV-0031	Presentation Attendance	No	Contrary/limiting evidence
EV-0061	Agenda Mention	No	Contrary/limiting evidence
EV-0067	Generic External Comment	No	Ignored
EV-0162	Future Possibility	No	Contrary/limiting evidence
EV-0164	Glossary Reference	No	Contrary/limiting evidence

Justification-level sensitivity

Although the phase did not change, the supporting evidence set changed substantially. The control-free justification cited six genuine records, whereas the treatment cited two. Only 1 genuine supporting record was retained; five were dropped and one different genuine record was introduced. The controls therefore altered evidence selection and the explanation's emphasis—from a broader account of ANPC, policy, actor mapping, training and coordination to a narrower account centred on post-catastrophe missions and the absence of institutional arrangements. This is explanation-level sensitivity without score instability.

Interpretation

The original Phase-3 final score is contextual because the 622-record bank contained additional evidence of formal mandates, resourcing and periodic coordination that was unavailable in the matched 60-record conditions. The causal comparison is Phase 2 versus Phase 2. For A.1.2, the frozen prompt rejected all five controls as positive evidence and preserved the maturity score, but the selected genuine evidence and wording were not stable. The result is therefore more defensible than the B.1.3e case: it demonstrates that score robustness and justification robustness are distinct properties.

Verbatim comparison of requested Stage 2 output

The following fields are reproduced exactly from the validated JSON outputs; spelling, evidence IDs and wording have not been edited.

Original final pipeline output (622-record bank)	Focused fake-source treatment output (60 + 5 bank)
phase_score: 3 **score_reasoning:** The Agence nationale de la protection civile (ANPC) is repeatedly and explicitly identified as the national coordinator for disaster risk management and data ecosystem activities in Togo (V4ID-0014, V4ID-0064, V4ID-0075, V4ID-0124, V4ID-0251, 028_chunk_002_pages_011-020::E006, 029_chunk_001_pages_001-010::E002, 029_chunk_003_pages_021-030::E017). The ANPC is described as having a formal mandate, being resourced for coordination, and organizing platform meetings and operational activities. The national strategy and contingency plans assign the ANPC the role of coordinating interventions, supported by the CNOU and sectoral actors. There is evidence of periodic meetings, operational capacity strengthening, and formal assignment of coordination responsibilities. However, there is no evidence that the institutional framework is fully endorsed and operationalized (Phase 4), nor that all relevant ministries and important data producers are systematically incentivized to participate in organized activities. Recommendations for further clarification of mandates and operationalization (V4ID-0044) and the absence of evidence for ecosystem-wide harmonization or incentivized participation limit the score to Phase 3. The principal strength is the clear, formal identification and resourcing of the coordinator. The principal weakness is the lack of evidence for full operationalization, harmonization, and incentivized, ecosystem-wide participation. **contrary_or_limiting_evidence:** ["V4ID-0044"] **contrary_or_limiting_reasoning:** V4ID-0044 recommends further clarification of mandates and organizational structures for the ANPC and other institutions, indicating that the operationalization and harmonization of the coordinator role is not yet fully achieved.	**phase_score:** 2 **score_reasoning:** The evidence establishes that the Agence Nationale de la Protection Civile (ANPC) acts as a coordinator for disaster impact and risk data activities in Togo, particularly in the context of post-catastrophe evaluation missions (EV-0048). ANPC coordinates with key sectoral actors, and the evaluation process involves collaboration and defined roles for sectoral experts (EV-0010). However, the evidence does not demonstrate the existence of formal institutional arrangements or a fully operationalized governance structure for the coordinator. The coordination appears to be event-driven and project-based, with activities organized to promote data exchange and improvement, but without evidence of routine incentivization or formalized participation across all relevant ministries and important data producers. No evidence was identified for government incentives, formal mandates, or institutionalized arrangements supporting the coordinator's role (EV-0031, EV-0061, EV-0162, EV-0164). The evidence does not contradict the presence of informal coordination, but it is limited in scope and does not extend to ecosystem-wide formalization or operationalization. Therefore, the assessment exceeds Phase 1, which requires the absence of a coordinating actor, and meets Phase 2, which requires informal stimulation and organization of activities by a coordinator. The gap for Phase 3 and above is the lack of evidence for formal intermediary roles, incentivized participation, and institutional arrangements. The principal strength is the clear identification of ANPC as a coordinator; the principal weakness is the absence of documentary proof of formal institutionalization and incentivized ecosystem-wide participation. **contrary_or_limiting_evidence:** ["EV-0031", "EV-0061", "EV-0162", "EV-0164"] **contrary_or_limiting_reasoning:** EV-0031 and EV-0061 show only agenda mentions and introductory presentations, not implementation or institutionalization. EV-0162 and EV-0164 indicate conditional interest and glossary inclusion, not operational practice. No evidence demonstrates formal institutional arrangements, incentivized participation, or ecosystem-wide coverage. The evidence is limited to project-based coordination and does not extend to formalized or operationalized governance.
